TITLE: High chromium steel for heat-resistant castings

SOURCE: Liteynoye proizvodstvo, no. 2, 1965, 9-10

TOPIC TAGS: steel casting, heat resistant casting, heat resistant steel, high  
chromium steel, steel mechanical property, steel weldability, casting strength/  
Kh21L sub ce steel, Kh24N12SL steel, Kh18N19TL steel

ABSTRACT: The authors describe the positive effect of additions (in unspecified  
proportions) of high-carbon scrap steel, low-carbon scrap ferrochromium, ferro-  
silicon, ferromanganese, scrap metal mixture and ferrocitinium on the  
mechanical properties of the resulting heat-resistant casting. The  
additions were made to the molten metal during casting. The following  
parameters were investigated: strength, weldability, heat resistance.  
The following parameters were investigated: strength, weldability, heat resistance.  
The following parameters were investigated: strength, weldability, heat resistance.  
the foundry were investigated: strength, weldability, heat resistance.

TITLE: Intensity of iron saturation in calorizing alloys and methods for refining them

SOURCE: Tekhnologiya i organizatsiya proizvodstva, no. 1, 1966, 43-46

TOPIC TAGS: aluminum containing alloy, metallurgic process, metal purification, binary alloy, temperature test, metal melting, intermetallic compound, iron containing alloy, metallurgy

ABSTRACT: The authors point out that the extent to which aluminum alloys are saturated by iron during calorizing has not been studied up to the present time and little effort has been made to develop methods for purifying these alloys. The problem of refining is important not only from the standpoint of producing binary alloy castings but also for purification of cast aluminum alloys in which iron is a harmful impurity.

Iron saturation was studied for pure aluminum and for aluminum alloys with 7.15 and 28% zinc, as well as in a zinc alloy with 0.2% aluminum since these

Card 1/4

UDC: 621.74.043:62:222

0916 10 46

L 34186-66

ACC NR: AP6026024

alloys are recommended for use in calorizing. Zinc alloy specimens with 0.2% aluminum were calorized at 535-545°C, aluminum alloys at 680-690 and 720-730°C and pure aluminum at 680-690, 720-730 and 780-790°C. Each specimen was held in the calorizing alloy for five minutes. After every five specimens had been calorized, metal samples weighing 8-10 g were removed from the vat for determining iron concentration. It was found that the specific rate of dissolution and the intensity of iron saturation are increased by raising the calorizing temperature. This is due to an increase in the activity of the melts with respect to iron (the degree of heating and the saturation limit of the iron melt increase.)

The specific rate for dissolving of cast iron in an aluminum alloy with 7% Zn shows the same relationship to iron concentration as for pure aluminum. An increase in temperature from 680-690 to 720-730°C has no effect on specific rate of dissolving. Specific rate of dissolving is increased by raising the zinc content in the melt and at a concentration of 28% the rate is the same as for pure aluminum. However, the relationship between specific rate of dissolving and iron concentration in the calorizing alloy is stronger and differs somewhat from that for pure aluminum.

A sharp reduction in the specific rate of dissolving is observed at iron concentrations below 1.0-1.4% as a function of the calorizing temperature. Beyond this point, there is some increase in the dissolving rate after which it remains practically constant. This type of behavior in the specific rate of dissolving as a function of iron concentration is due to the extreme iron deficiency

Card 2/4

134186-65

ACC NR: AP6026024

(0.012-0.018%) in the eutectic of the Zn-Fe system and the formation of intermetallic compounds at rather low iron concentrations. The formation of Fe-Zn and Fe-Al intermetallic compounds (and possibly more complex systems) stabilizes the rate of dissolving. A zinc alloy with 0.2% aluminum yields satisfactory results in calorizing cast iron and steel. Iron saturation of this alloy is much lower than for aluminum or aluminum-zinc alloys. The specific rate of dissolution for iron in this alloy is also very low and increases somewhat with an increase in iron concentration in the alloy. Low iron saturation intensity in a Zn+0.2%Al alloy is due to the low calorizing temperature. Thus, the bath is quite highly saturated with iron during calorizing of steel in aluminum and aluminum alloys.

Two refining methods were tested: settling and filtering. Both methods are based on a reduction in the solubility of iron in aluminum and its alloys when the temperature is reduced. During settling, excess iron which is separated out in the form of aluminides or zincates is precipitated to the bottom of the vat due to its higher specific gravity. In the case of filtering, these iron compounds are retained by the filter for the same reason. Pure aluminum and aluminum-zinc alloy with 28% zinc with various initial iron concentrations were refined. The settling and filtering processes were carried out at a temperature 10-15°C above the solidus temperature. The settling time was four hours. Fusion of the refined alloys with zinc (up to 72% Zn) was used for reducing the

Card 3/4

ACC NR: AP6026024

solidus temperature. It was found that filtering is an extremely effective refining process and is simpler and less expensive than the settling method. This method is particularly recommended for refining aluminum alloys containing zinc (Al+5-28% Zn and several cast alloys, e.g., Al111, Al114, Al115V, etc.), since the addition of up to 72% zinc to these alloys results in an extremely high purification from iron. TITLE: Mechanism of growth of NaCl whiskers

SOURCE: AN BSSR. Fiziko-tehnicheskiy institut. Plastichnost' i oorabotka  
metallov davleniyem (Plasticity and metalworking by pressure). Minsk, Izd-vo  
Nauka i tekhnika, 1964, 257-260

TOPIC TAGS: filamentary crystal, whisker growth, sodium chloride whisker, whisker  
strength

ABSTRACT: Filamentary crystals, or whiskers, of NaCl were grown by two methods:  
in a saturated solution of NaCl with the addition of polyvinyl alcohol and through  
a porous partition. In the first method 1% polyvinyl alcohol (by weight) was  
added to a saturated solution of salt; after which it was heated to the boiling  
point. Then the solution was cooled and filtered. A seed was inserted into the flask with  
the solution and the temperature was raised to 140°C. The speed of  
growth of the whiskers was dependent upon the temperature, the concentration of the  
solution, pressure of the water vapor, and the surface area.

Card 1/3

ACCESSION NR: AT5006716

O

experiments showed that even a negligible temperature fluctuation (from 10 to 27°C) led to a change in the growth rate of the whiskers. With slow evaporation the growth rate reached 1 cm per day. Their cross section was square with sides from several to 100  $\mu$  with a size ratio of 1 : 1. In the second method, with crystallization through a porous partition, whiskers did not grow in the initial period. In subsequent periods they grew at a rate which was less than that of the whiskers from the solution with polyvinyl alcohol. When in the whisker tube the NaCl root the porous partition took place at the bottom of the saturated solution at half height along capillary pores in the interior of the glass porous partition. Due to evaporation this solution became supersaturated and crystallization centers formed that were commensurate with the size of the capillary pores. Once a NaCl crystal that was formed filled the diameter of the capillary, it was pushed out by hydrodynamic forces; the unsaturated solution was again supersaturated, the NaCl was deposited on the root of the already formed crystal, and the solid phase was again pushed out. This growth continued until the weight of the crystal reached a certain magnitude above which the whisker could not adhere to the root in the capillary and dropped of its own weight. The length of the whiskers thus

Card 2/3

L 3997 -00

ACCESSION NR: AT5006716

grown reached 1.5-2.0 cm and their thickness varied from 5 to 100  $\mu$ . Mechanical tests showed that the strength was independent of the dependence of strength on the cross section of the whisker. The best quality NaCl whisker had a elastic limit of about 1.4% and tensile strength of about  $63 \text{ kg/mm}^2$ , which is about 1000 times greater than for the usual NaCl crystals. TITLE: Once More on the Adjustment of PSBN-m Without the Use of Corner  
Reflectors (Yeshche raz o yustirovke PSBN-m bez ugolkovogo  
otrazhatelya)

PERIODICAL: Vestnik vozduzhnogo flota, 1959, Nr 4, pp 86-87 (USSR)

ABSTRACT: The author states that the method of adjusting PSBN-m /radar bomb-sight/ without the use of corner reflectors, as recommended by Capt V. G. Serdyukov in his article "Adjusting PSBN-m without the use of Corner Reflectors" (was published in issue Nr 9 of this periodical in 1958), can be used as an auxiliary method. The method with the use of corner reflectors should be considered as the basic one and the adjustment of PSBN-m by this method should be carried out after 50-hour routine maintenance operations.

Title : The Phase Development of Cucumbers

Orig Pub : Agrobiologiya, 1956, No 5, 149-150

Abstract : The Vegetable Frowing Institute has studied during 1951-1954 the peculiarities of growth, development and fruitbearing of cucumbers of the Nerosimye variety in relation to its seedling cultivation conditions. During the study of the vernalization phase the temperature and the moisture of the seeds were modified, and during the study of the light phase, the temperature, air humidity and length of day. Vernalization of the seeds at temperatures of 22-26° and a humidity of 50% accelerated the plant development somewhat; however, no structural change of any kind during the periods of growth until the end of vernalization has been observed. With unlimited seed dampness (moistening for 12 h. in water at room temperature), the appearance of flower tubercles was noted. These changes

Card : 1/2

took place faster by raising the temperature from 14.4 to 21°. In a 10-12 h. day at temperatures of 20-25° in the daytime and 15-18° at night and the humidity of air at 85-95%, the plants started to bloom 2-3 days earlier and increased the yield on an average of 8-10% as compared with plants developed at 17-19° at daytime and 12-14° at night and air humidity of 70-80% in a 16-17 h. day.

TITLE: Operating Experience With and Comparative Evaluation of Reinforced-  
Concrete-Frame Hotbeds Having Various Systems of Heating  
(Opyt ekspluatatsii i sravnitel'naya otsenka parnikov s zhelezobetonnymi  
parubnyami i razlichnymi sistemami tekhnicheskogo obogreva)

PERIODICAL: Byul. nauchno-tekh. inform. N.-i. in-ta ovoshchn. kh-va,  
1957, Vol 2, pp 23-26

ABSTRACT: After a 3-year testing of hotbeds, the following conclusions were drawn: (1) reinforced-concrete frames are preferable to wooden; (2) the best heating method proved to be central water heating with 3-5 atm steam; (3) hotbeds with electrode-type heating are simpler and cheaper than others. Electric-energy consumption per sash for the season from the beginning of March is about 80 kw-hr, and from mid-March, 40 kw-hr. Roof-iron electrodes can

Card 1/2

SOV/112-59-3-5147

Operating Experience With and Comparative Evaluation of Reinforced-Concrete . . . .

serve for 2 seasons. Connecting wires should be of copper because aluminum wires crumble. The standard electric-heating project must be revised: safety of personnel, as well as other improvements, must be secured. Technically-heated hotbeds require 2-2.5 times less labor than biological-fuel hotbeds. The CO<sub>2</sub> content in the technically-heated hotbeds should be artificially increased. The article presents a table giving a comparison of characteristics of hotbeds with various methods of heating and giving coal consumption for central water heating.

TITLE: Utilization of gas-kinetics phenomena for measuring the surface temperature of heated bodies

SOURCE: Ukrayins'kyy fizichnyy zhurnal, v. 10, no. 2, 1965, 206-210

TOPIC TAGS: surface temperature measurement, radiometric effect, thermocouple, accommodation coefficient, temperature measurement JM

ABSTRACT: A method is presented for indirect determination of the surface temperature of heated bodies to which conventional temperature measuring methods are not applicable, e.g., crystals growing by sublimation; the oxide layer of thermal insulators, luminescent discs, etc. While the method is not applicable to all substances, it is based on the previously postulated radiometric effect (M. Knudsen, Z. Phys., v. 34, 823, 1911). The surface to be measured (A) is placed in a vacuum opposite a second body (B) of the same size and shape but made of a material to which a thermocouple method is applicable. A thin metal foil is suspended between the two bodies, a small mirror is placed at the junction of the suspender supports. The pressure on each side of the foil will depend on the temperature of the two

Card 1/2

L 27402-65

ACCESSION NR: AP5005915

bodies. At different temperatures, the foil deviates from its original position, and the degree of deviation is registered on a scale on which a light is reflected from the mirror. When the temperature of body B has been measured, the temperature of body A can be calculated by the equation:  $T_1 = T_2 \cdot e^{Y_1/Y_2}$ , where  $T_1$  is the temperature of body A;  $T_2$  is the temperature of body B; and  $Y_1$  and  $Y_2$  refer to the accuracy coefficients of the two bodies. The sensitivity of the method depends on the sensitivity of the thermocouple used, on the pressure, and on the temperature of the two bodies. The method, which may also be used for determining the density of the body, is applicable at pressures ranging from  $10^{-3}$  to 1 mm Hg. [Fig. 4] (PS) has: 1 figure and 9 formulas.

TITLE: Determination of the energy of optical radiation by  
means of selective receptorsPERIODICAL: Ukrayins'kyy fizychnyy zhurnal, v. 7, no. 11, 1962,  
1226-1229TEXT: If the spectral sensitivity of a selective receiver  
is  $S(\lambda)$  and the spectral distribution of the incident radiation is  
 $\epsilon(\lambda)$ , the indications of the receiver will be

$$n = \alpha_1 \int_0^{\infty} S(\lambda) \epsilon(\lambda) d\lambda$$

The indication of a nonselective ideal photoactinometer are

$$n_{ph} = \alpha \int_{380}^{710} \epsilon(\lambda) d\lambda.$$

Card 1/2

Determination of the energy ...

S/185/62/007/011/012/019  
D234/D308

The purpose of the paper was to reduce the indications of various receivers to those of an ideal photoactinometer by means of  $n/n_{ph}$ . Numerical values of the integrals were found graphically using spectral curves of various receivers and sources of radiation (those for incandescence lamps were calculated from black body radiation with corrections taken from a paper by Forsythe and Adams). A table of energy equivalents of a lux for various sources and of sensitivities of receivers (referred to that of an ideal photoactinometer) to various sources is added. There are 2 tables.

TITLE: Physical bases for measurements of the energy of photosynthetically active radiation with selective instruments

CITED SOURCE: Fiziol. rasteniy, v. 10, no. 5, 1963, 598-602

TOPIC TAGS: photosynthesis, solar radiation, radiation measurement, solar energy, photometer, photoactinometer, actinometry

TRANSLATION: The goal of this work was the evaluation of the relative sensitivity of existing instruments for the measurement of photosynthetically active radiation and the calculation of the corresponding corrective coefficients to adjust their readings to the readings of an ideal photoactinometer. The readings on the instruments depend essentially on the source of radiation, which is connected with the different distribution of energy in the spectra of the radiation sources. Usually, radiation sensors are rated under a heating lamp with a color temperature of 2850K. In this connection, in this paper, corrective coefficients are given for conversion of the readings of different instruments under

Card 1/2

ABSTRACT: This Author Certificate presents a device for the automatic verification  
of angle-code converters. The device includes a reference converter and the  
converter under examination, both of which are rotated by a single motor through  
a reduction drive. The device also includes a circuit for comparison of the code  
signals. This device provides simultaneous verification of all code paths and  
automates the process of initially setting the converters. The registers which  
store the codes of the reference converter and the converter under examination  
are connected through a circuit of discharge comparison of the codes to the

TITLE: Determination of the Surface Cracking Resistance of  
Transparent Plastic Materials on Wedge-shaped Samples

PERIODICAL: Zavodskaya laboratoriya, 1960, Vol. 26, No. 12,  
pp. 1390-1391

TEXT: The surface cracking resistance may be characterized by means of the tensile stress, at which the first visible cracks occur within a given time interval after application of load, or by determining the surface under stress in the case of a pure bending test, at which the first cracks occur. A further possibility is offered by the occurrence of cracks on the surface of plastic materials sometimes after having been wetted with organic liquids. For being able to judge the surface cracking resistance, these methods are, however, unsuited. V. R. Regel' (Ref. 7) suggests the curve  $\tau = f(\sigma)$ , i.e., the determination of the time interval  $\tau_0$  from the instant of stress being applied to the sample up to the occurrence of the first cracks as a function of the tensile stress  $\sigma$  for the purpose of characterizing the surface

Card 1/3

on Wedge-shaped Samples

cracking resistance of plastic materials. In the present paper, it is also suggested to characterize surface cracking resistance by means of the relation  $\tau_o = f(\sigma)$ , where the sample has the shape of a truncated wedge. The cracks at first occur in the narrow sections of the sample, and only later on the broader sections. A cracking front forms, which gradually shifts from the narrower to the broader sections of the sample. The width of the sample at the place of the "front" is periodically measured, the time since the beginning of the stress is noted, and from the thickness of the sample and the tensile force, the tensile stress corresponding to  $\tau_o$  is calculated. The wedge-shaped samples (Fig. 1) were sawed with a circular saw. The angle of the wedge was about  $5^\circ$ , the maximum width of the sample was 8-9 mm, and its minimum width 3 to 3.5 mm. The thickness of the samples was 1-4 mm, and their full length 55-60 mm. Before the experiments were made, the samples were heated to a temperature, which was higher by  $10 - 20^\circ$  than the fusion point of the given material. In the case of the shape of the samples selected, the stress dropped from the minimum to the maximum section to about the half of its former amount. The results obtained

Resistance of Transparent Plastic Materials      S/032, 6/026/012/018/036  
on Wedge-shaped Samples      B020/B056

by wedge-shaped and ordinary samples were in good agreement (Fig. 2). For the purpose of calculating the relation  $\tau_0 = f(\sigma)$ , in the first case two, and in the second case 11 samples were used. The total time needed for the investigation, using a test cell, was in the first case about 8, and in the second case about 18 hours. Title : A Polarographic Determination of the Number of Electrons Participating  
in the Electrochemical Reduction of Bismuth in Alloys

Orig Pub: Zh. Neorgan. Khimii, 1956, Vol 1, No 4, 710-712

Abstract: The polarogram for BiCl<sub>3</sub> in a melt made up of an equimolar mixture  
of AlBr<sub>3</sub> and NaCl has been recorded with a fixed tungsten electrode;  
the polarogram shows a clear single wave. The graph E vs. log  
 $\sqrt{i(i_d-i)}$  is a straight line with a slope of 0.048 v; this slope  
corresponds to the reaction Bi<sup>3+</sup> + 2e  $\rightleftharpoons$  Bi<sup>+</sup>. The absence of in-  
flexion points on the curve which would correspond to the reduction  
of Bi<sup>+</sup> indicates the instability of BiCl.

TITLE: Determination of the diffusion coefficients of metals in amalgams

PERIODICAL: Zhurnal fizicheskoy khimii, v. 37, no. 3, 1963, 538-543

TEXT: The authors aimed at using nonstationary processes of anodic dissolution of liquid alloys to determine the diffusion coefficients of metals in alloys. In the present paper the determination of the diffusion coefficients of Cd, Pb, and Zn in their amalgams is studied by nonstationary diffusion currents. A geometrical consideration shows that the equation  $i = zFC_0 A \sqrt{D/\pi\tau}$  for diffusion from a semiinfinite space into a plane surface can be applied for the meniscus of amalgam (radius = 0.9cm).  $A = 4\pi R^2$  is the electrode surface and D is the diffusion coefficient. A description is given of the measurement of electrode surface by evaluating its photograph or by determining the diffusion current of an ion whose D is exactly known. The oscillographs

Showed the linear dependence between  $i$  and  $\sqrt{D/\tau}$ ;  $D = (i/\tau) \sqrt{\pi/zFC_0 A}^2$ , where  $i/\tau$  is the tangent of the slope of the straight lines, holds for the diffusion coefficient. Linearity is preserved up to 0.8 sec, but longer duration of electrolysis causes deviation owing to convection currents. The authors obtained  $D = 2.45 \cdot 10^{-5}$  for Cd,  $3.15 \cdot 10^{-5}$  for Pb, and  $1.9 \cdot 10^{-5}$  cm<sup>2</sup>/sec for Zn at 20°C. The apparent activation energy of diffusion is 1695 cal/mole (15-80°C) for Cd, 1910 cal/mole (15-50°C) for Zn, and 2800 cal/mole (15-50°C) for Pb. There are 7 figures.

TITLE: On the Grüneisen coefficient

PERIODICAL: Fizika tverdogo tela, v. 5, no. 3, 1963, 886-890

TEXT: The Grüneisen coefficient (ratio between thermal pressure and thermal energy density) is usually calculated by one of the following formulas

$$\gamma_s = -\frac{2}{3} - \frac{V}{2} \frac{\frac{d^2}{dV^2} P_s}{\frac{d}{dV} P_s}, \quad (\text{Slater})$$

$$\gamma_{DM} = -\frac{1}{3} - \frac{V}{2} \frac{\frac{d^2}{dV^2} (P_s V^{1/3})}{\frac{d}{dV} (P_s V^{1/3})}. \quad (\text{Dugdale-McDonald})$$

Card 1/5.

On the Grüneisen coefficient

S/181/63/005/003/028/046  
B102/B180

$$\gamma_f = -\frac{V}{2} \frac{\frac{d^2}{dV^2}(P_s V^{1/4})}{\frac{d}{dV}(P_s V^{1/4})} \quad (\text{theory of the free volume})$$

The accuracy of the assumptions made on the derivation of these relations is discussed. The weak dependence of Poisson's ratio  $\mu$  on the volume, in particular, has a considerable effect on Slater's result. Due to the difference in longitudinal and transverse frequencies in the Debye spectrum

$$\gamma_L = -\frac{d \ln \omega_L}{d \ln V} \quad \text{and} \quad \gamma_T = -\frac{d \ln \omega_T}{d \ln V}, \quad (4)$$

$$\omega_L \sim \frac{c_L^3}{V^{1/4}} \sim V^{1/4} \frac{1-\mu}{1+\mu} \frac{dP_s}{dV}; \quad \omega_T \sim \frac{c_T^3}{V^{1/4}} \sim V^{1/4} \frac{1-2\mu}{1+\mu} \frac{dP_s}{dV}. \quad (5)$$

one obtains

B102/B180

$$\left. \begin{aligned} \gamma_1 &= -\frac{4-3n}{6} - \frac{V}{2} \frac{\frac{d^2}{dV^2} (P_x V^n)}{\frac{d}{dV} (P_x V^n)}, \\ \gamma_2 &= -\frac{4-3m}{6} - \frac{V}{2} \frac{\frac{d^2}{dV^2} (P_x V^m)}{\frac{d}{dV} (P_x V^m)}, \end{aligned} \right\} m = \frac{3}{2} \frac{1-\mu_0}{1-2\mu_0} n. \quad (8)$$

where  $\mu_0$  is the  $\mu$  value at  $P_x=0$ . / for  $P_x=0$  is then given by

$\gamma_s^0 = \frac{n}{6} \frac{4-5\mu_0}{1-2\mu_0}$ ,  $\gamma_s^0$  being the / value at  $P_x=0$ .  $\mu(V)$  may be determined from  $\gamma_s^0$  and  $\gamma_{exp}^0$ : When  $\gamma_{exp}^0 < \gamma_s^0$ ,  $\mu$  increases on compression ( $n > 0$ ) when  $\gamma_{exp}^0 > \gamma_s^0$ ,  $\mu$  decreases ( $n < 0$ ). Up to now only three metals, Pt, Pb and Au, are known for which  $\gamma_{exp}^0 > \gamma_s^0$ . The  $\gamma_{DM}$  formula was obtained from the Card 3/5.

(13).

The latter relations agree with the initially given  $\gamma_f$  formula. For crystalline argon and KCl  $\gamma_f(v)$  ( $v$  as a function of the lattice constant  $d$ ) is calculated according to Born's theory and compared with  $\gamma_s$ ,  $\gamma_{DM}$ ,  $\gamma_f$ ;  $\gamma_f(v)$  lies closest to the Born curve. For KCl the divergence increases with decreasing  $d$ , due to a phase transition. There are 2 figures.

TITLE: Equation of state of cesium iodide

SOURCE: Fizika tverdogo tela, v. 7, no. 4, 1965, 1212-1215

TOPIC TAGS: equation of state, cesium iodide, shock adiabat, electron excitation, thermodynamic property

ABSTRACT: This is a continuation of an investigation of CsI which was started earlier ("Fizika tverdogo tela", where the shock compression was investigated at a pressure of 4.0 g/cm<sup>2</sup> and porous samples with density 4.0 g/cm<sup>3</sup> were used). The samples (density 4.0 g/cm<sup>3</sup> and porosity 1.8) were used, and the test procedure was described in detail in the earlier paper. An equation of state is derived with the aid of the free-volume theory, which is based on the assumption that the density of the sample is constant.

Waals forces, the Coulomb forces, and the overlap forces. Shock adiabats are plotted under various assumptions and the results prove the large role played by anharmonicity in the thermodynamic quantities. The contribution of electron-electron excitation to the thermodynamic quantities is estimated for high temperatures (but lower than the width of the forbidden band). The result is that the electrons have a strong influence at high temperatures agrees qualitatively with the parabolic and with the results obtained by the molecular orbital method, with less detail. Results for LiF will be given in figure, tables and text.
